

IN2009  
Language Processors

Session 10

## Stack Frames

Igor Siveroni

## Schedule

- **Revision class & Test**  
**Monday 26th April 2010 (11.00-13.00)**  
**Room C340**
  - 11:00-12:00 Revision part 1
  - 12:00-12:30 Test3  
Type-checking and stack frames.  
Sample questions on Wednesday.
  - 12:30-13:00 Test3 solution
- All results ready on May 3.

19th April, 2010

IN2009 Language Processors - Session 10

2

## Schedule

- **Exam**  
**June 2, 14:30-16:00**
  - Choose 2 out of 3 questions. 100 points each.
  - Based on test1, test2 and test3.
  - ... more during revision class.
- No Lab today.

19th April, 2010

IN2009 Language Processors - Session 10

3

## Session Plan

### Session 6: Stack Frames

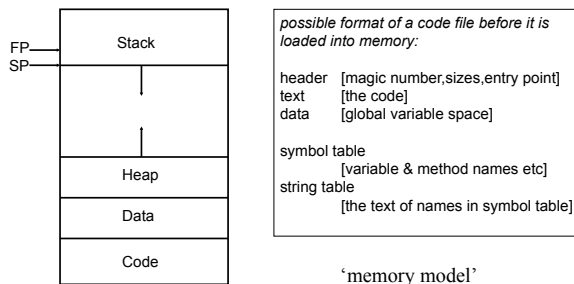

- Memory Model
- Stack frames
  - layout
  - frame pointer and stack pointer
  - parameter passing
- TPL representation
- Example

19th April, 2010

IN2009 Language Processors - Session 10

4

## Layout in memory

19th April, 2010

IN2009 Language Processors - Session 10

5

## Stack Frames

- Functions/procedures may have *local* variables
- Several invocations at same time each with own instantiations of local variables - e.g. recursive calls, and arguments.
- Local variables destroyed on method return
- LIFO behaviour (implemented with stack data structure)

```
int f(int x) {
    int y = x+x;
    if y < 10
        return f(y);
    else
        return y-1;
}
```

- New instantiation of x created & initialised by f's caller each time f called
- Recursive calls - many x's exist simultaneously
- New instantiation of y created each time body of f entered

19th April, 2010

IN2009 Language Processors - Session 10

6

## Stack frames

- **Stack frames:** Needed due to the existence of procedures and recursion in a programming language
- Stack frames save the state of execution of a procedure/function: A snapshot of a procedure's state.
- Frame layout design
  - Takes into account particular features of instruction set architecture and programming language being compiled

19th April, 2010

IN2009 Language Processors - Session 10

7

## Stack frames

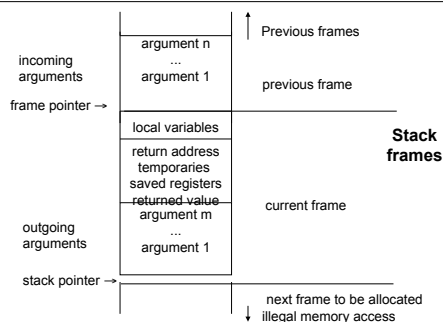

- Usually a standard frame layout prescribed by manufacturer
  - not necessarily convenient for compiler writers, but...
  - functions/methods written in one language can call functions/methods written in another, so...
  - gain programming language interoperability
  - can combine modules/classes compiled from different languages in same running program

19th April, 2010

IN2009 Language Processors - Session 10

8

## Stack frames

19th April, 2010

IN2009 Language Processors - Session 10

9

## Stack frame layout

- Set of *incoming arguments* (part of previous frame) passed (stored) by caller code
- Return address: location where execution resumes after method return.
- Local variables (those not in registers)
- Temporaries - locations where code temporarily saves intermediate values (if registers not available)

19th April, 2010

IN2009 Language Processors - Session 10

10

## Stack frame layout

- Saved registers: Area for values held in registers that need to be saved when a procedure call is made. Registers are restored when procedure returns.
- Returned value: Place where the callee stores the value returned by the procedure/function.
- Outgoing argument space: to pass (store) parameters when procedure calls other procedures.

19th April, 2010

IN2009 Language Processors - Session 10

11

## Parameter passing

- Pre-1960: passed in statically allocated memory blocks - no recursive functions or methods
- 1970s machines: function arguments passed on the stack
- But program analysis shows that very few functions/methods have >4 arguments, and almost none >6.

19th April, 2010

IN2009 Language Processors - Session 10

12

## Parameter passing

- So on most modern machines
  - first  $k$  arguments ( $k=4$  or  $6$ ) are passed in registers  $r_p, \dots, r_{p+k-1}$  and the rest passed in memory on the stack
- But in our case (SPL and TPL) we will pass all arguments on the stack.

19th April, 2010

IN2009 Language Processors - Session 10

13

## Procedure call. Steps:

**Caller  $g(\dots)$  calls callee  $f(a_1, \dots, a_n)$ :**

- Calling code in  $g$  puts arguments to  $f$  at end of  $g$  frame
- Registers (if necessary) are stored in  $g$ 's frame.
- Return address is saved in  $g$ 's frame
- On entry to  $f$ ,
  - SP points to first argument  $g$  passes to  $f$
  - old SP becomes current *frame pointer* FP
  - $f$  then allocates frame by setting  $SP = (SP + \text{framesize})$

19th April, 2010

IN2009 Language Processors - Session 10

14

## Procedure call...steps

- Old SP becomes current *frame pointer* FP
- Many implementations have FP as a separate register
  - so method code:
    - has incoming arguments referenced by FP-an offset
    - has local variables referenced by FP+an offset
    - has saved registers, return address and outgoing arguments referenced by FP+an offset or SP-an offset

19th April, 2010

IN2009 Language Processors - Session 10

15

## Procedure return

- Callee saves returned value in caller's frame.
- On exit from  $f$ :  $SP = FP$ , removing frame.
- Code in  $g$  restores registers (if any).
- Execution (in  $g$ ) resumes from return address.

19th April, 2010

IN2009 Language Processors - Session 10

16

## Implementation in TPL

- Procedure call:  
**call label, framesize**  
Where label is the location of the callee's code, and framesize is the size of the callee's stack frame
- Method return:  
**return**  
variation: **return Arg**  
With return value.

19th April, 2010

IN2009 Language Processors - Session 10

17

## Implementation in TPL

- We will assume that the size (in memory) of values are:
  - Integer, boolean and addresses: 1 word
  - Float: 2 words
- The size of values is important to determine the total size of the frame.
- We will assume that there's a dedicated FP register.

19th April, 2010

IN2009 Language Processors - Session 10

18

## Implementation in TPL

- Given a variable *x* located at an *offset* from FP, we can access the variable by combining FP with *offset*.
- For example:
  - **store 20, FP(offset)**  
stores 20 to variable *x*
  - **store FP(offset), R1**  
stores the contents of *x* into register R1.

19th April, 2010

IN2009 Language Processors - Session 10

19

## Example

```
int f(int x) {
    float y, z;
    int w;
    y = (float) (10*x);
    z = g(10, y);
    // more code...
    // no more calls
    return w;
}

float g(int a,
        float b) {
    // g's body
    return 10.0;
}
```

- We'll assume that there's enough registers (no need to save them)
- **f** stack frame. size = 11
  - location 0: var *y* (size 2)
  - location 2: var *z*
  - location 4: var *w*
  - location 5: return address
  - location 6: g's returned value
  - location 8: g param *b*, offset 3
  - location 10: g param *a*, offset 1

19th April, 2010

IN2009 Language Processors - Session 10

20

## Example

- From *f*:
  - **STORE 5, FP(-1)**  
stores 5 to parameter *x* (integer)
  - **STORE FP(2), R2**  
stores value of local variable *z* into register R2 (float)
- From *g*:
  - **ADDI FP(-1), 2, R3**  
adds 2 to value of parameter *a* (integer), and stores result in register R3
  - **STORE 10.0, FP(-5)**  
stores 10.0 in location reserved for returned value of *g*.

19th April, 2010

IN2009 Language Processors - Session 10

21

## Example

- Test 3 will:
  - Contain a similar question: given a code sample, provide the stack frame structure.
  - Ask you to list type errors present in a piece of code.
  - Ask you to define the type checks for a new statement or expression.

19th April, 2010
