UNIVERSITY OF EDINBURGH

FACULTY OF SCIENCE AND ENGINEERING

COMPUTER SCIENCE THREE

COMPILING TECHNIQUES

Thursday 8 June 2000 14:00 to 15:30

Examiners:

Prof. K. Turner (External)

Prof. G. Brebner (Chairman)

INSTRUCTIONS TO CANDIDATES

Answer any TWO questions.

All questions carry equal weight.

1. (a) Explain what it means for a context-free grammar to be *ambiguous*, and why this is undesirable for grammars used to specify the syntax of programming languages.

[4 marks]

(b) Consider the following grammar:

$$\begin{array}{ccc} E & \rightarrow & E\,B\,E \\ E & \rightarrow & \mathsf{num} \\ E & \rightarrow & (E) \\ B & \rightarrow & + \\ B & \rightarrow & - \\ B & \rightarrow & * \\ P & & & \\ \end{array}$$

i. Explain why this grammar is not suitable to form the basis for a recursive descent parser.

[3 marks]

ii. Use left-factoring and left-recursion removal to obtain an equivalent grammar which can be used as the basis for a recursive descent parser.

[5 marks]

- iii. Assuming procedures to check for lexical items such as num, write a recursive descent parser for your grammar in part (ii).
- [5 marks]
- (c) Write an unambiguous grammar for statement blocks as in ML, where the semi-colons *separate* the statements. E.g.

```
(statement; (statement; statement); statement)
```

[4 marks]

(d) Write an unambiguous grammar for statement blocks as in C, where the semi-colons *terminate* the statements. E.g.

{expression; {expression; expression; } expression; }

[4 marks]

2. (a) Each function call during the execution of a program causes a *stack frame* to be allocated. Describe the layout of a typical stack frame, identifying the different kinds of values which are stored there.

[5 marks]

(b) State conditions under which a local variable of a function is said to *escape* from that function. How does a variable escaping affect how it can be stored?

[3 marks]

(c) For each of the variables a, b, c, d, e in the following C program, say whether they should be kept in memory or a register, and why.

```
int f(int a, int b)
{ int c[5], d, e;
  d = a+c[2];
  e = g(&b, c);
  return b + e;
}
```

[5 marks]

[7 marks]

- (d) Explain the concept of a *static link*. Give an example of a Tiger program to illustrate the use of static links.
- (e) Which class of functions in Tiger do *not* need a static link passed to them? [5 marks]

3. (a) Describe the liveness analysis phase of compilation. Explain its purpose, and outline how it is performed.

[5 marks]

[5 marks]

- (b) Explain the distinction between *dynamic* and *static* liveness, and the sense in which the liveness analysis performed by a compiler gives a *conservative* approximation of the dynamic semantics. Why is this unavoidable?
- (c) Consider the following program:

```
a := 0
L1:c := a+1
    d := a+c
    b := 2*d
    a := b-d
    if a<3 then goto L2
    c := a
    goto L1
L2:return c</pre>
```

(i) Draw the control-flow graph for this program.

[3 marks]

(ii) Calculate the live-in and live-out at each node of the graph.

[5 marks]

(iii) Draw the register interference graph.

[2 marks]

(d) Based on the analysis of part (c), how could later phases of compilation optimise the storage requirements and run-time of the program?

[5 marks]
